Abstract

Dimensional reduction of various gravity and supergravity models leads to effectively two-dimensional field theories described by gravity coupled $\mathbf{G}/\mathbf{H}$ coset space σ -models. The transition matrices of the associated linear system provide a complete set of conserved charges. Their Poisson algebra is a semi-classical Yangian double modified by a twist which is a remnant of the underlying coset structure. The classical Geroch group is generated by the Lie-Poisson action of these charges. Canonical quantization of the structure leads to a twisted Yangian double with fixed central extension at a critical level.

*On leave of absence from Steklov Mathematical Institute, Fontanka, 27, St.Petersburg 191011, Russia.

1 Introduction

The last decade has shown the important role of infinite-dimensional quantum groups in physics, providing a powerful description of the quantum symmetries of integrable models and field theories. A prominent example is the Yangian algebra $Y(\mathfrak{g})$ associated with a simple finite-dimensional Lie algebra $\mathfrak{g}$. Having turned up already in the early days of the Quantum Inverse Scattering Method [50, 19] this algebra was rigorously defined within the framework of Hopf algebras by Drinfeld [14] and later on appeared to underlie many two-dimensional field theories (see [5, 7] and references therein). The Yangian algebra $Y(\mathfrak{g})$ may be considered as a deformation of the positive half of a loop algebra with nontrivial Hopf algebra structure. For $\mathfrak{g} = \mathfrak{gl}(N)$ it allows the representation by matrix entries $T^{ab}(w)$ of $N \times N$ matrices with exchange relations

$$R(v-w) \overset{1}{T}(v) \overset{2}{T}(w) = \overset{2}{T}(w) \overset{1}{T}(v) R(v-w) , \quad (1.1)$$

with a rational R -matrix solving the Yang-Baxter equation. A deformation of the full loop algebra emerges from the Yangian double construction [15] which has been introduced in quantum field theory in [38, 6]. Like the full loop algebra this structure admits a central extension [48, 30, 27].

In this paper we reveal Yangian symmetries in a class of models of quantum gravity. Actually, it is the existence of this symmetry in the corresponding sectors of the classical theory which allows their complete quantization. The relevant sectors descend from dimensional reduction of various gravity and supergravity theories. As effectively two-dimensional theories they are given by different $\mathbf{G}/\mathbf{H}$ coset space σ -models coupled to $2d$ gravity and a dilaton. Among them (with $\mathbf{G}/\mathbf{H} = SL(2, \mathbb{R})/SO(2)$) is the two Killing vector field reduction of pure $4d$ Einstein gravity. Its field content is given by a symmetric 2×2 -matrix g with unit determinant, which parametrizes the $4d$ line element

$$ds^2 = e^{2\Gamma(\rho, t)} (-dt^2 + d\rho^2) + \rho g_{ab}(\rho, t) dx^a dx^b . \quad (1.2)$$

The accompanying dilaton factor ρ is a typical feature of Kaluza-Klein-like dimensional reductions; here it has already been identified with a coordinate (the so-called Weyl's canonical coordinates). Upon further truncation to diagonal g this model reduces to the Einstein-Rosen waves whose quantization was studied in [36, 2]. Other examples with higher-dimensional coset spaces $\mathbf{G}/\mathbf{H}$ come from Einstein-Maxwell systems [31, 21] or maximally extended supergravity [29].

The equations of motion for all these models are given by the Ernst equation

$$\partial_0(\rho g^{-1} \partial_0 g) - \partial_1(\rho g^{-1} \partial_1 g) = 0 , \quad (1.3)$$

with a $\mathbf{G}$ -valued matrix g subject to additional coset restrictions. For $SL(2, \mathbb{R})/SO(2)$, g alternatively coincides with the symmetric matrix from (1.2) or with a matrix carrying the dualized potentials of the Ernst picture [17]. Up to the prefactor of ρ the Ernst equation equals the dynamics of the $2d$ nonlinear σ -model [40, 18, 41]. However, it is exactly this factor which essentially changes many of the properties of the model and gives rise to several new features.

In particular, it turns out, that in our model the non-ultralocal contributions of the canonical Poisson brackets do not cause an obstacle for a well-defined Poisson structure between the generating functions of the integrals of motion. This allows a reformulation of the classical model in terms of a complete set of nonlocal conserved charges $T_{\pm}(w)$ defined as holomorphic matrix functions in the upper resp. the lower half of the complex plane. A consistent and essentially unique canonical quantization of the complete structure for $\mathfrak{g} = \mathfrak{sl}(N)$ leads to the following new algebra of Yangian type:

$$\begin{aligned} R(v-w) \overset{1}{T}_{\pm}(v) \overset{2}{T}_{\pm}(w) &= \overset{2}{T}_{\pm}(w) \overset{1}{T}_{\pm}(v) R(v-w) , \\ R(v-w - i\hbar) \overset{1}{T}_{-}(v) \overset{2}{T}_{+}(w) &= \overset{2}{T}_{+}(w) \overset{1}{T}_{-}(v) R^{\eta}(v-w + \frac{2}{N}i\hbar) \chi(v-w) . \end{aligned} \quad (1.4)$$

In contrast to the known centrally extended Yangian double based on (1.1) the mixed exchange relations here contain an R -matrix R^η which is obtained from $R(v-w) \in \mathcal{U}(\mathfrak{g}) \otimes \mathcal{U}(\mathfrak{g})$ by “twisting” one of the two spaces with the algebra involution η which characterizes the underlying coset structure. The values of the central extension as well as the rescaling factor $\chi(v)$ in (1.4) are uniquely fixed. We call this algebra a twisted centrally extended Yangian double at critical level.

A crucial role in our model is played by the matrix product

$$\mathcal{M}(w) = T_+(w)T_-^t(w) , \quad (1.5)$$

which in some sense behaves similar to the quantum current introduced in [48] for the normal Yangian double. This matrix coincides with the values of the original field g from (1.3) at $\rho = 0$. This is the symmetry axis if ρ is chosen as radial coordinate; for timelike ρ it describes the (cosmological) origin. Thus, the matrix $\mathcal{M}(w)$ is localized in the $2d$ spacetime though at a fixed instant of time it is defined in a highly nonlocal way. It provides a surprising link between the conserved charges and the physical fields. In particular, the algebra (1.4) is compatible with the symmetry of (1.5).

The present paper generalizes and gives a detailed account of the results which were partially announced in [34, 35]. It is organized as follows. In Chapter 2 we give the Lagrangian formulation of the models, derive equations of motion and the canonical Poisson structure. Chapter 3 is devoted to the key calculation of the Poisson algebra between the transition matrices of the associated linear system. In Chapters 4 and 5 we evaluate this result to obtain a complete set of conserved charges and their Poisson algebra after gauge fixing of the dilaton to a spacelike resp. timelike coordinate. Chapter 6 recovers the transitive action of the Geroch group which in this framework is generated by the Lie-Poisson action of the classical algebra of charges. The heart of the paper is Chapter 7 where we present the quantum model for $\mathfrak{g} = \mathfrak{sl}(N)$. Quantizing the classical Poisson algebra we uniquely obtain (1.4) and show its consistency with all additional structures. In Chapter 8 we discuss in more detail the simplest case $\mathfrak{g} = \mathfrak{sl}(2)$ related to reduced Einstein gravity (1.2). Chapter 9 briefly summarizes the solved and the remaining problems.

2 Canonical Formalism

Let Σ be a two-dimensional Lorentzian world-sheet, parametrized by coordinates x^μ . We introduce light-cone coordinates $x^\pm \equiv x^0 \pm x^1$. Let $\mathbf{G}$ be a semisimple Lie group and $\mathfrak{g}$ the corresponding Lie algebra with basis t_a . Denote by $\mathbf{H}$ the maximal compact subgroup of $\mathbf{G}$, characterized as the fixgroup of an involution η . Lifting η to the algebra gives rise to the decomposition

$$\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{k} \quad \text{with} \quad \eta(X) = \begin{cases} X & \text{for } X \in \mathfrak{h} \\ -X & \text{for } X \in \mathfrak{k} \end{cases} , \quad (2.1)$$

which is orthogonal with respect to the Cartan-Killing form.

The physical fields of the model are mappings $\mathcal{V}(x^\mu)$ from Σ into the coset space $\mathbf{G}/\mathbf{H}$, i.e. they are $\mathbf{G}$ -valued and exhibit the gauge freedom of right $\mathbf{H}$ -multiplication. The currents $J_\mu \equiv J_\mu^a t_a \equiv \mathcal{V}^{-1} \partial_\mu \mathcal{V}$ allow decomposition according to (2.1):

$$J_\mu = Q_\mu + P_\mu ; \quad \text{with} \quad Q_\mu \in \mathfrak{h} , \quad P_\mu \in \mathfrak{k} , \quad (2.2)$$

such that the gauge transformations take the form

$$Q_\mu \mapsto h^{-1} Q_\mu h + h^{-1} \partial_\mu h , \quad P_\mu \mapsto h^{-1} P_\mu h , \quad (2.3)$$

with $h = h(x^\mu) \in \mathbf{H}$.

Let us establish the canonical setting. The dimensional reduction of gravity and supergravity theories has already and often been described in the literature (see e.g. [29, 9, 45]). Hence, we here restrict to starting from the effectively two-dimensional reduced theory given by $2d$ dilaton gravity

coupled to different nonlinear $\mathbf{G}/\mathbf{H}$ coset space σ -models corresponding to different original theories. The remaining (reduced and gauge-fixed) Lagrangian is of the form

$$\mathcal{L} = \frac{1}{2} \rho \operatorname{tr} (P_\mu P^\mu) = \frac{1}{2} \rho \operatorname{tr} (P_0^2 - P_1^2) , \quad (2.4)$$

In addition to the coset currents P_μ from (2.2) there appears a dilaton field ρ related to the compactified part of the former higher-dimensional metric, which obeys the $2d$ Laplace equation

$$\square \rho = 0 . \quad (2.5)$$

At this stage of reduction ρ is no longer a canonical field, but has already been gauge-fixed to a particular solution of (2.5) on the world-sheet Σ . Define its dual $\tilde{\rho}$ by $\partial_\mu \tilde{\rho} = -\epsilon_{\mu\nu} \partial^\nu \rho$.¹ In the sequel, we will often make use of the Weyl gauge choice, i.e. identify $\rho, \tilde{\rho}$ with the world-sheet coordinates x^μ .

The Lagrangian (2.4) resembles the one of the principal chiral field model (PCM) [40, 18] with the group $\mathbf{G}$ of the PCM replaced by the coset manifold $\mathbf{G}/\mathbf{H}$ and arising of the additional dilaton field ρ which is in fact responsible for all the differences that will appear in contrast to the PCM already on the classical level. Nevertheless, we may introduce the canonical framework in an analogous way. Treat the current $J_1(x)$ as canonical coordinates; its time derivative is expressed via the condition of vanishing curvature:

$$\partial_0 J_1 = \partial_1 J_0 + [J_1, J_0] \equiv \nabla_1 J_0 .$$

Note, that the operator ∇_1 is antisymmetric with respect to the scalar product $(\operatorname{tr} \int dx^1)$. The action thus reads

$$\begin{aligned} \frac{1}{2} \int \rho \operatorname{tr} (P_\mu P^\mu) dx^0 dx^1 &= \frac{1}{2} \int \rho \operatorname{tr} (P_0 \nabla_1^{-1} (\partial_0 J_1) - P_1^2) dx^0 dx^1 \\ &= -\frac{1}{2} \int \operatorname{tr} ((\partial_0 J_1) \nabla_1^{-1} (\rho P_0) - \rho P_1^2) dx^0 dx^1 . \end{aligned}$$

Introduce the corresponding momenta $\pi_J \equiv \pi_Q + \pi_P$ with canonical Poisson structure

$$\left\{ J_1^a(x), \pi_J^b(y) \right\} = \delta^{ab} \delta(x-y) ,^2 \quad (2.6)$$

at equal times. From the action it follows that

$$\rho P_0 = -\nabla_1 \pi_J = -\partial_1 \pi_J - [J_1, \pi_J] ,$$

which according to (2.1) gives rise to

$$\rho P_0 = -\partial_1 \pi_P - [Q_1, \pi_P] - [P_1, \pi_Q] , \quad (2.7)$$

$$0 = -\partial_1 \pi_Q - [Q_1, \pi_Q] - [P_1, \pi_P] \equiv \phi . \quad (2.8)$$

The first equation expresses a part of the coordinates' time derivatives in terms of the canonical momenta; the second equation forms a set of (first-class) constraints, that exactly generate the gauge transformations (2.3).

For further calculations, we switch to the index-free tensor notation. Denote for some matrix X :

$$X^1 \equiv X \otimes I \quad \text{and} \quad X^2 \equiv I \otimes X .^3$$

¹We use the convention $\epsilon_{01} = \epsilon^{10} = 1$ for the antisymmetric ϵ -symbol and $\eta_{\mu\nu} = \operatorname{diag}(1, -1)$ for the $2d$ Minkowski metric.

²Here and in the following we denote for simplicity the spatial coordinate x^1 by x only and the timelike coordinate x^0 by t .

³In components this takes the form $(X \otimes I)^{ab,cd} \equiv X^{ab} \delta^{cd}$ and $(I \otimes X)^{ab,cd} \equiv X^{cd} \delta^{ab}$.

Define accordingly the following matrix notation of Poisson brackets [20]:

$$\left\{ \begin{smallmatrix} 1 \\ A \end{smallmatrix}, \begin{smallmatrix} 2 \\ B \end{smallmatrix} \right\}^{ab,cd} \equiv \{A^{ab}, B^{cd}\}, \quad (2.9)$$

for matrices A^{ab}, B^{cd} . Let $\Omega_{\mathfrak{g}} \equiv t_a \otimes t^a$ be the Casimir element of $\mathfrak{g}$, which due to orthogonality of (2.1) allows the decomposition $\Omega_{\mathfrak{g}} = \Omega_{\mathfrak{h}} + \Omega_{\mathfrak{k}}$. The canonical brackets (2.6) in this notation become

$$\left\{ \begin{smallmatrix} 1 \\ Q_1 \end{smallmatrix}(x), \begin{smallmatrix} 2 \\ \pi_Q \end{smallmatrix}(y) \right\} = \Omega_{\mathfrak{h}} \delta(x-y), \quad \left\{ \begin{smallmatrix} 1 \\ P_1 \end{smallmatrix}(x), \begin{smallmatrix} 2 \\ \pi_P \end{smallmatrix}(y) \right\} = \Omega_{\mathfrak{k}} \delta(x-y).$$

Equ. (2.7) now yields the Poisson brackets for the physical fields:

$$\begin{aligned} \left\{ \begin{smallmatrix} 1 \\ P_0 \end{smallmatrix}(x), \begin{smallmatrix} 2 \\ \mathcal{V} \end{smallmatrix}(y) \right\} &= -\frac{1}{\rho(x)} \begin{smallmatrix} 2 \\ \mathcal{V} \end{smallmatrix}(x) \Omega_{\mathfrak{k}} \delta(x-y), \\ \left\{ \begin{smallmatrix} 1 \\ P_0 \end{smallmatrix}(x), \begin{smallmatrix} 2 \\ Q_1 \end{smallmatrix}(y) \right\} &= \frac{1}{\rho(x)} \left[\Omega_{\mathfrak{k}}, \begin{smallmatrix} 2 \\ P_1 \end{smallmatrix}(x) \right] \delta(x-y), \\ \left\{ \begin{smallmatrix} 1 \\ P_0 \end{smallmatrix}(x), \begin{smallmatrix} 2 \\ P_1 \end{smallmatrix}(y) \right\} &= \frac{1}{\rho(x)} \left[\Omega_{\mathfrak{k}}, \begin{smallmatrix} 2 \\ Q_1 \end{smallmatrix}(x) \right] \delta(x-y) + \frac{1}{\rho(x)} \Omega_{\mathfrak{k}} \partial_x \delta(x-y), \\ \left\{ \begin{smallmatrix} 1 \\ P_0 \end{smallmatrix}(x), \begin{smallmatrix} 2 \\ P_0 \end{smallmatrix}(y) \right\} &= \frac{1}{\rho(x)} \left[\Omega_{\mathfrak{h}}, \begin{smallmatrix} 2 \\ \phi \end{smallmatrix}(x) \right] \delta(x-y) \approx 0. \end{aligned} \quad (2.10)$$

Moreover, it follows from (2.8) that the constraints $\phi(x)$ indeed build a closed algebra

$$\left\{ \begin{smallmatrix} 1 \\ \phi \end{smallmatrix}(x), \begin{smallmatrix} 2 \\ \phi \end{smallmatrix}(y) \right\} = \frac{1}{\rho(x)} \left[\Omega_{\mathfrak{h}}, \begin{smallmatrix} 2 \\ \phi \end{smallmatrix}(x) \right] \delta(x-y), \quad (2.11)$$

and infinitesimally generate the gauge transformations (2.3). They obviously leave the Lagrangian (2.4) invariant.

Remark 2.1 The Poisson brackets (2.10) are the canonical Poisson brackets derived from the Lagrangian (2.4) which in turn descends from a consistent dimensional reduction of the higher-dimensional Lagrangian of the original theory. Thus, this Poisson structure comes from proper reduction of the symplectic structure of the original theory.

Another important feature to note about the Poisson brackets (2.10) is the appearance of a non-ultralocal term in the third equation. In the known flat space integrable models the presence of such a term is a good indicator for some breakdown of the conventional techniques at later stage (see e.g. [13] for exploring the fatal consequences of the non-ultralocal term in the PCM). However, for our model we will see that this term shows a surprisingly good behavior and in fact supports the entire further treatment.

Finally, we can discuss the dynamics of the model. The equations of motion derived from (2.4) are

$$D^\mu(\rho P_\mu) = D_0(\rho P_0) - D_1(\rho P_1) = 0, \quad (2.12)$$

with the covariant derivative $D_\mu P_\nu \equiv \partial_\mu P_\nu + [Q_\mu, P_\nu]$. In terms of the field $g \equiv \mathcal{V}\eta(\mathcal{V})^{-1} \in \mathbf{G}$ this becomes the more familiar form of the Ernst equation [17]

$$\partial^\mu(\rho g^{-1} \partial_\mu g) = \partial_0(\rho g^{-1} \partial_0 g) - \partial_1(\rho g^{-1} \partial_1 g) = 0. \quad (2.13)$$

The Hamiltonian of the model comes out to be

$$H = \frac{1}{2} \int \rho \operatorname{tr} (P_0^2 + P_1^2) dx. \quad (2.14)$$

There are two points to mention about the Hamiltonian dynamics here. Note first that H does not govern the possible explicit time-dependence of ρ . This is due to the fact that in course of the reduction leading to (2.4) the system has become nonautonomous due to the particular gauge-fixing of the dilaton ρ to a function with explicit time-dependence. It implies in particular that H generates the equations of motion only for the fields (ρP_0) and P_1 . Secondly, H generates the dynamics of these fields only up to gauge transformations (2.3) as can be explicitly checked. This corresponds to the fact that as a Hamiltonian of a constrained system H is determined only up to a linear combination of the arising first-class constraints (2.11).

3 Poisson Algebra of Transition Matrices

In this and the following chapters we will exploit the integrability of the model to define and explore the transition matrices to be used as the fundamental objects in the sequel. The model (2.4) is integrable in the sense that it possesses a linear system [4, 42]; i.e. the equations of motion (2.12) appear as integrability conditions of the following linear system of differential equations:

$$\partial_\mu \hat{\mathcal{V}}(x, t, \gamma) = \hat{\mathcal{V}}(x, t, \gamma) L_\mu(x, t, \gamma) , \quad (3.1)$$

with

$$L_\mu(x, t, \gamma) = Q_\mu + \frac{1 + \gamma^2}{1 - \gamma^2} P_\mu + \frac{2\gamma}{1 - \gamma^2} \epsilon_{\mu\nu} P^\nu ,$$

and

$$\gamma(x, t, w) = \frac{1}{\rho} \left(w + \tilde{\rho} - \sqrt{(w + \tilde{\rho})^2 - \rho^2} \right) .$$

The PCM admits a similar linear system with constant spectral parameter γ [47, 52]. The difference here which is essential for the entire following treatment is the coordinate dependence of γ and its interplay with the underlying constant parameter w . Some useful and illustrative formulas are collected in Appendix A.

The existence of the linear system allows the construction of the transition matrices

$$T(x, y, t, w) \equiv \hat{\mathcal{V}}^{-1}(x, t, \gamma(x, t, w)) \hat{\mathcal{V}}(y, t, \gamma(y, t, w)) .$$

They satisfy:

$$\begin{aligned} T(x, x, t, w) &= I , \\ \partial_x T(x, y, t, w) &= -L_1(x, t, \gamma(x, t)) T(x, y, t, w) , \\ \partial_y T(x, y, t, w) &= T(x, y, t, w) L_1(y, t, \gamma(y, t)) , \\ \partial_t T(x, y, t, w) &= -L_0(x, t, \gamma(x, t)) T(x, y, t, w) + T(x, y, t, w) L_0(y, t, \gamma(y, t)) . \end{aligned} \quad (3.2)$$

Like the spectral parameter γ , the transition matrices also live on a twofold covering of the complex w -plane. Transition between the two sheets is performed by the involution η . Until explicitly stated, we shall in the following always consider the sheet with $\gamma \in D_+ \cup D_-$ inside of the unit circle (cf. Appendix A).

Note, that $T(x, y, t, w)$ is uniquely determined by the first three equations of (3.2); its time-dependence is a consequence of the equations of motion (2.12). If the physical currents and thus L_0 vanish sufficiently fast at spatial infinity, (3.2) already shows, that the transition matrices connecting the spatial boundaries become integrals of motion. They shall in fact play the main role in the sequel. The rest of this chapter will be spent to calculate their Poisson algebra.

Let $T(x, y, v)$ and $T(x', y', w)$ be the transition matrices with spectral parameters v and w respectively and pairwise distinct endpoints x, y and x', y' .⁴ Equ. (3.2) implies the well-known formula [20]

$$\left\{ \overset{1}{T}(x, y, v), \overset{2}{T}(x', y', w) \right\} = \int_x^y dz \int_{x'}^{y'} dz' \left(\overset{1}{T}(x, z, v) \overset{2}{T}(x', z', w) \right) \quad (3.3)$$

$$\left\{ \overset{1}{L}_1(z, \gamma(z, v)), \overset{2}{L}_1(z', \gamma(z', w)) \right\} \left(\overset{1}{T}(z, y, v) \overset{2}{T}(z', y', w) \right).$$

Due to the underlying coset structure of the model, it is already far from obvious, that the Poisson algebra of the connection L_1 of the linear system (3.1) is of a closed form. However, this comes out to be true on the constraint surface (2.8):

$$\left\{ \overset{1}{L}_1(x, \gamma_1), \overset{2}{L}_1(y, \gamma_2) \right\} = -\frac{2\gamma_1\gamma_2}{\rho(\gamma_1 - \gamma_2)(1 - \gamma_1\gamma_2)} \left[\Omega_{\mathfrak{h}}, \overset{1}{L}_1(\gamma_1) + \overset{2}{L}_1(\gamma_2) \right] \delta(x - y)$$

$$- \frac{2\gamma_2^2(1 - \gamma_1^2)}{\rho(1 - \gamma_2^2)(\gamma_1 - \gamma_2)(1 - \gamma_1\gamma_2)} \left[\Omega_{\mathfrak{k}}, \overset{1}{L}_1(\gamma_1) \right] \delta(x - y)$$

$$- \frac{2\gamma_1^2(1 - \gamma_2^2)}{\rho(1 - \gamma_1^2)(\gamma_1 - \gamma_2)(1 - \gamma_1\gamma_2)} \left[\Omega_{\mathfrak{k}}, \overset{2}{L}_1(\gamma_2) \right] \delta(x - y)$$

$$- \frac{2\Omega_{\mathfrak{k}}}{(1 - \gamma_1^2)(1 - \gamma_2^2)} \left(\frac{\gamma_1(1 + \gamma_2^2)}{\rho(x)} + \frac{\gamma_2(1 + \gamma_1^2)}{\rho(y)} \right) \partial_x \delta(x - y),$$

with $\gamma_1 \equiv \gamma(x, v)$, $\gamma_2 \equiv \gamma(y, w)$. Inserting this into (3.3) finally leads to the following result:

$$\left\{ \overset{1}{T}(x, y, v), \overset{2}{T}(x', y', w) \right\} = \quad (3.4)$$

$$\frac{1}{v - w} \times \left\{ \theta(x, x', y) \left(\overset{1}{T}(x, x', v) \Omega_{\mathfrak{h}} \overset{1}{T}(x', y, v) \overset{2}{T}(x', y', w) \right) \right.$$

$$+ \theta(x', x, y') \left(\overset{2}{T}(x', x, w) \Omega_{\mathfrak{h}} \overset{1}{T}(x, y, v) \overset{2}{T}(x, y', w) \right)$$

$$- \theta(x, y', y) \left(\overset{1}{T}(x, y', v) \overset{2}{T}(x', y', w) \Omega_{\mathfrak{h}} \overset{1}{T}(x, y, v) \right)$$

$$\left. - \theta(x', y, y') \left(\overset{1}{T}(x, y, v) \overset{2}{T}(x', y, w) \Omega_{\mathfrak{h}} \overset{2}{T}(y, y', w) \right) \right\}$$

$$+ \frac{\theta(x, x', y)}{v - w} \left(\overset{1}{T}(x, x', v) \Omega_{\mathfrak{k}} \overset{1}{T}(x', y, v) \overset{2}{T}(x', y', w) \right) \frac{\gamma(x', v)(1 - \gamma^2(x', w))}{\gamma(x', w)(1 - \gamma^2(x', v))}$$

$$+ \frac{\theta(x', x, y')}{v - w} \left(\overset{2}{T}(x', x, w) \Omega_{\mathfrak{k}} \overset{1}{T}(x, y, v) \overset{2}{T}(x, y', w) \right) \frac{\gamma(x, w)(1 - \gamma^2(x, v))}{\gamma(x, v)(1 - \gamma^2(x, w))}$$

$$- \frac{\theta(x, y', y)}{v - w} \left(\overset{1}{T}(x, y', v) \overset{2}{T}(x', y', w) \Omega_{\mathfrak{k}} \overset{1}{T}(x, y, v) \right) \frac{\gamma(y', v)(1 - \gamma^2(y', w))}{\gamma(y', w)(1 - \gamma^2(y', v))}$$

$$- \frac{\theta(x', y, y')}{v - w} \left(\overset{1}{T}(x, y, v) \overset{2}{T}(x', y, w) \Omega_{\mathfrak{k}} \overset{2}{T}(y, y', w) \right) \frac{\gamma(y, w)(1 - \gamma^2(y, v))}{\gamma(y, v)(1 - \gamma^2(y, w))},$$

where we have made use of the abbreviation:

$$\theta(x, y, z) = \begin{cases} 1 & \text{for } x < y < z \\ 0 & \text{else} \end{cases}.$$

Although during the calculation several additional terms arise due to the explicit coordinate dependence of the spectral parameter γ , the result takes a similar form similar as in the PCM. At first

⁴For clearness we drop the (coinciding) argument t for the rest of this chapter.

sight, we thus face the same fatal problem: With distinct endpoints x, x', y, y' the algebra is uniquely and well defined, satisfying in particular antisymmetry and Jacobi identities. For coinciding endpoints on the other hand equ. (3.4) obviously gives an ambiguous answer, e.g. for $x = x'$ due to the different coefficients of $\theta(x', x, y')$ and $\theta(x, x', y)$. In the PCM this further leads to ambiguities in the limit $x, x' \rightarrow -\infty, y, y' \rightarrow \infty$ with no possibility to restore it in accordance with antisymmetry and validity of Jacobi identities [40, 13].⁵

In our model however, the coordinate dependence of the spectral parameter changes the situation drastically. Note first, that the part of (3.4) related to the subalgebra $\mathfrak{h}$ and thus revealing the underlying coset structure (the first four lines) allows a unique limit to coinciding endpoints. The remaining terms invoke the spectral parameters v and w in combinations of the form

$$\frac{\gamma(x, w)(1 - \gamma^2(x, v))}{\gamma(x, v)(1 - \gamma^2(x, w))} = \sqrt{\frac{(v + \tilde{\rho})^2 - \rho^2}{(w + \tilde{\rho})^2 - \rho^2}}. \quad (3.5)$$

This shows the interesting consequence of the explicit coordinate dependence of γ : if at spatial infinity the fields ρ or $\tilde{\rho}$ diverge — like they do for the choice of Weyl's canonical coordinates — all these terms tend to ± 1 . In particular, they become independent of v and w , thus (3.4) possesses a well defined and unique limit for coinciding endpoints at spatial infinity. As a result, the Poisson algebra (3.4) for these transition matrices takes a treatable form that is related to the well-known Yangian algebra [14]. We shall study this in detail for fixed choices of ρ and $\tilde{\rho}$ in the subsequent chapters.

4 Spacelike Dilaton

Assuming the vector field $\partial_\mu \rho$ to be globally spacelike, we now identify ρ with the radial coordinate $x = r \in [0, \infty[$. This is a usual choice of coordinates for describing cylindrically symmetric gravitational waves [36, 2]. The dual field $\tilde{\rho}$ then is identified with the time t .

Consider the object

$$\hat{\mathcal{V}}_1(r, t, \gamma(w)) \equiv \mathcal{V}(r=0, t)T(0, r, t, w), \quad (4.1)$$

with $\gamma \in D_+ \cup D_-$ inside of the unit circle.

According to (3.2) and (A.5), this is a solution of the linear system (3.1). A closer look at the properties of the spectral parameter (cf. Appendix A) shows, that it is the unique solution which is holomorphic inside of the unit circle in the γ -plane.⁶

Let us assume, that the physical currents J_μ fall off sufficiently fast at spatial infinity $r \rightarrow \infty$. In this limit, $\hat{\mathcal{V}}_1$ then becomes t -independent. As a function of w it becomes discontinuous along the real w -axis (since the branch cut blows up and cuts the plane into two halves). We denote them by

$$T_\pm(w) \equiv \overline{T_\mp(\bar{w})} \equiv \mathcal{V}(r=0, t)T(0, \infty, t, w) \quad \text{for } \gamma(w) \in D_\pm. \quad (4.2)$$

These constants of motion $T_\pm(w)$ will provide the new variables of the model. As functions of the constant spectral parameter w they are holomorphic in the upper resp. lower half of the complex plane. We can still bring them into a more illustrative form. Starting from

$$T_\pm(w) = \mathcal{V}(r=0, t) \mathcal{P} \exp \int_0^\infty \left(Q_1 + \frac{1 + \gamma^2}{1 - \gamma^2} P_1 - \frac{2\gamma}{1 - \gamma^2} P_0 \right) dr,$$

the t -independence may be exploited to calculate this expression for real w at the specific value $t = -w$ (assuming regularity of the currents):

$$T_\pm(w) = \mathcal{V}(r=0, t=-w) \mathcal{P} \exp \int_0^\infty \left(Q_1(r, -w) \pm i P_0(r, -w) \right) dr. \quad (4.3)$$

⁵Several procedures have been suggested to nevertheless give sense to the classical Poisson algebra of the PCM [18, 16, 41].

⁶This normalization for the solution of the linear system has e.g. been chosen in [8].

Thus, on the real w -axis $T_{\pm}(w)$ naturally factorizes into the product of a real and a compact part. It follows, that the matrix product

$$\mathcal{M}(w) \equiv \lim_{\epsilon \rightarrow 0} \left(T_+(w+i\epsilon) \eta(T_-^{-1}(w-i\epsilon)) \right), \quad \text{for } w \in \mathbb{R}, \quad (4.4)$$

peels off the compact part of the factorization (4.3) and thus coincides with the values of the original field on the symmetry axis $r=0$:

$$\mathcal{M}(w) = \mathcal{V}(r=0, t=-w) \eta(\mathcal{V}^{-1}(r=0, t=-w)) = g(r=0, t=-w). \quad (4.5)$$

In particular, it is real

$$\mathcal{M}(w) = \overline{\mathcal{M}(w)}, \quad (4.6)$$

and satisfies

$$\mathcal{M}(w) = \eta(\mathcal{M}(w))^{-1}. \quad (4.7)$$

Vice versa, (4.4) can be interpreted as the essentially unique (Riemann-Hilbert) factorization of $\mathcal{M}$ into a product of matrices holomorphic in the upper and the lower half of the complex w -plane respectively.⁷

Equ. (4.5) provides a physical interpretation for the new constants of motion. Having been defined as spatially nonlocal charges for fixed t , they gain a definite localization in the $2d$ spacetime at fixed r . Moreover, they contain the entire information about the solution: Together with the fact that $(\partial_r \mathcal{V})(r=0) = 0$ which follows from the equations of motion (2.12), the values on the symmetry axis $r=0$ allow to recover the field $\mathcal{V}$ everywhere. In some sense the initial values on a spacelike surface have been transformed into initial values along a timelike surface. Thus, the $T_{\pm}(w)$ build a complete set of constants of motion for this classical sector of solutions regular on the symmetry axis.

It remains to calculate the Poisson structure of the $T_{\pm}(w)$. The result (3.4) in this case simplifies considerably. The first four terms become

$$\left[\frac{\Omega_{\mathfrak{h}}}{v-w}, T^1(v) T^2(w) \right],$$

for arbitrary indices $\pm$ at the T 's. The next two terms contain γ depending on the left boundaries x, x' and tend to distinct fixed values. The arising ambiguity at $x=x'$ however is precisely cancelled by the additional contributions from the brackets $\{T(x, y, v), \mathcal{V}(x')\}$ and $\{\mathcal{V}(x), T(x', y', w)\}$ in the limit $x, x' \rightarrow 0$. Only the last two terms are sensitive to the choice of indices $\pm$. In the limit $y, y' \rightarrow \infty$, the corresponding combinations of the form (3.5) tend to $+1$ if $\gamma(v)$ and $\gamma(w)$ lie in the same of the two regions D_+ and D_- , whereas they tend to -1 otherwise (cf. (A.5)).

The final result is the following Poisson structure:

$$\left\{ T_{\pm}^1(v), T_{\pm}^2(w) \right\} = \left[\frac{\Omega_{\mathfrak{g}}}{v-w}, T_{\pm}^1(v) T_{\pm}^2(w) \right], \quad (4.8)$$

$$\left\{ T_{\pm}^1(v), T_{\mp}^2(w) \right\} = \frac{\Omega_{\mathfrak{g}}}{v-w} T_{\pm}^1(v) T_{\mp}^2(w) - T_{\pm}^1(v) T_{\mp}^2(w) \frac{\Omega_{\mathfrak{g}}^{\eta}}{v-w}, \quad (4.9)$$

with $\Omega_{\mathfrak{g}}^{\eta} \equiv \Omega_{\mathfrak{h}} - \Omega_{\mathfrak{k}}$ obtained from $\Omega_{\mathfrak{g}}$ by applying η in one of the two spaces. Eqs. (4.8) build two semi-classical copies of the Yangian algebra that is well known from other $2d$ field theories [5, 6, 7]. By semi-classical we conventionally mean that the Poisson brackets (4.8) coincide with the commutator of the $\hbar$ -graded Yangian algebra in first order $\hbar$. The mixed relations (4.9) appear “twisted” by the involution η with respect to those coming from the normal Yangian double. Note that

⁷The matrix $\mathcal{M}(w)$ in fact coincides with the so-called monodromy matrix of $\hat{\mathcal{V}}_1$, originally introduced in [8]. It is related to the transformation behavior of $\hat{\mathcal{V}}_1$ between the two sheets of γ and may in particular be extracted from $\hat{\mathcal{V}}_1$ already at finite r .

whereas (4.8) remains regular at coinciding arguments, (4.9) becomes obviously singular at $v = w$. However, since T_+ and T_- are defined in distinct domains, this singularity appears only in the limit on the real line and thus with a well-defined $i\epsilon$ -prescription.

The matrices $\mathcal{M}(w)$ form a closed Poisson algebra:

$$\begin{aligned} \left\{ \overset{1}{\mathcal{M}}(v) , \overset{2}{\mathcal{M}}(w) \right\} &= \frac{\Omega_{\mathfrak{g}}}{v-w} \overset{1}{\mathcal{M}}(v) \overset{2}{\mathcal{M}}(w) + \overset{1}{\mathcal{M}}(v) \overset{2}{\mathcal{M}}(w) \frac{\Omega_{\mathfrak{g}}}{v-w} \\ &\quad - \overset{1}{\mathcal{M}}(v) \frac{\Omega_{\mathfrak{g}}^{\eta}}{v-w} \overset{2}{\mathcal{M}}(w) - \overset{2}{\mathcal{M}}(w) \frac{\Omega_{\mathfrak{g}}^{\eta}}{v-w} \overset{1}{\mathcal{M}}(v) . \end{aligned} \quad (4.10)$$

The singularity at $v = w$ is understood in the principal value sense. For consistency, it may be checked that (4.10) is indeed compatible with the symmetry (4.7) of $\mathcal{M}$.

Summarizing, the variables $\mathcal{M}(w)$ provide a new formulation of the model based on the closed Poisson algebra (4.10) and a physical interpretation according to (4.5). The further study and quantization of this structure will start from the factorization (4.4) with the corresponding Poisson algebra (4.8), (4.9).

Let us finally compute the Poisson brackets between the Hamiltonian of (2.14) with the new variables $T_{\pm}$. Though they are integrals of motion they do not commute with H , since their definition makes explicit use of the time $t = \tilde{\rho}$. The standard formula

$$\left\{ \overset{1}{T}(x, y, v) , \overset{2}{X} \right\} = \int_x^y dx' \overset{1}{T}(x, x', v) \left\{ \overset{1}{L}_1(x', \gamma(x', v)) , \overset{2}{X} \right\} \overset{1}{T}(x', y, v) , \quad (4.11)$$

for arbitrary X , allows to explicitly calculate the Poisson bracket

$$\{T_{\pm}(w), H\} = \partial_w T_{\pm}(w) . \quad (4.12)$$

This result also follows from a simple reasoning: due to the form (A.1) of the spectral parameter γ and the definition (3.2), the explicit time dependence of the $T_{\pm}(w)$ (the one which is not governed by H) equals their w -dependence. Since they are integrals of motion, their bracket with H then takes the form (4.12).

5 Timelike Dilaton

In this chapter we study the case of a globally timelike vector field $\partial_{\mu}\rho$, which allows to identify ρ with the time t . Accordingly, $\tilde{\rho}$ now builds the spatial coordinate x . The distinguished location $\rho = 0$ which has played the role of the symmetry axis $r = 0$ in the previous chapter becomes now the origin $t = 0$. With periodic spatial topology, this is the setting of the so-called cosmological Gowdy-models [24].⁸ We will however just treat the asymptotic case $x \in]-\infty, \infty[$. The fundamental structures of the preceding chapter reappear in this context from a somewhat different side. We keep the technical issues rather briefly here since they have been discussed in detail above.

Again the transition matrices $T(x, y, t, w)$ provide a solution of the linear system:

$$\hat{\mathcal{V}}_2(x, t, \gamma(w)) \equiv T(-\infty, x, t, w) , \quad (5.1)$$

for $\gamma(w) \in D_+ \cup D_-$ inside of the unit circle. It gives rise to the integrals of motion

$$T(w) \equiv T(-\infty, \infty, t, w) . \quad (5.2)$$

With (A.5) and (3.4) it follows that they satisfy the Poisson algebra

$$\left\{ \overset{1}{T}(v) , \overset{2}{T}(w) \right\} = \left[\frac{\Omega_{\mathfrak{g}}}{v-w} , \overset{1}{T}(v) \overset{2}{T}(w) \right] . \quad (5.3)$$

⁸See [26, 43] for a recent treatment of the Gowdy model in Ashtekar variables.

In contrast to the previous chapter this function is continuous in the w -plane (since the branch-cut does not blow up in the limit $x \rightarrow \infty$ but rather moves along the real line). Moreover, they do not contain the complete information about the model. This may be seen most easily for solutions of (2.12) which are regular at the origin $t = 0$. For these solutions (5.2) can be calculated in the limit $t \rightarrow 0$ where it becomes trivial. Since it is t -independent we arrive at

$$T(w) = I . \quad (5.4)$$

Thus, additional integrals of motion are required. Define

$$\mathcal{M}(w) = \lim_{\epsilon \rightarrow 0} \left(\hat{\mathcal{V}}_2(x, t, \gamma(w + i\epsilon)) \eta \left(\hat{\mathcal{V}}_2^{-1}(x, t, \gamma(w - i\epsilon)) \right) \right) , \quad (5.5)$$

which is independent of x and t . This is the proper analogue of (4.4). In fact within the setting of the previous chapter definition (5.5) with $\hat{\mathcal{V}}_2$ replaced by $\hat{\mathcal{V}}_1$ equals (4.4): the latter one is obtained from the former one in the limit $r \rightarrow \infty$ while $\mathcal{M}$ is independent of r . In the case of timelike ρ on the other hand, (5.5) cannot be expressed in terms of (5.2) (as is obvious from (5.4)). This is due to the fact that the limits $\epsilon \rightarrow 0$ and $x \rightarrow \infty$ do not interchange in (5.5), cf. Appendix A.

For the solutions regular at the origin $t=0$, $\mathcal{M}(w)$ can again be calculated more explicitly. Since $\mathcal{M}(w)$ is independent of x and t , we may evaluate it at the branchpoint $x \equiv t-w$ and subsequently perform the limit $t \rightarrow 0$. It is important to keep $x = t-w$ during the limit process, since otherwise $\mathcal{M}(w)$ does not behave smoothly. This yields:

$$\begin{aligned} \mathcal{M}(w) &= \lim_{t \rightarrow 0, x=w-t} \left(\mathcal{P} \exp \int_{-\infty}^x dx L_1(x, \gamma) \mathcal{P} \exp \int_{-\infty}^x dx \eta \left(L_1(x, \gamma) \right) \right) \\ &= \mathcal{V}(x=-w, t=0) \eta \left(\mathcal{V}(x=-w, t=0) \right) . \end{aligned} \quad (5.6)$$

Thus, $\mathcal{M}(w)$ again coincides with the values of the physical field g at $\rho=0$.

The set of $\mathcal{M}(w)$ together with their canonical Poisson structure (4.10) provides a proper set of fundamental variables to parametrize the phase space of solutions of (2.12) regular at the origin $t=0$. Note, that the canonical formulation obviously fails to cope with describing this truncated phase space: At $t=0$ this framework breaks down with the vanishing Lagrangian (2.4), whereas at finite t the condition of regularity at $t=0$ poses highly nontrivial implicit relations between the canonical coordinates and the momenta.

After some calculation, the general form of the Poisson brackets (3.4) further yields the same Poisson algebra (4.10) as in the previous chapter for the matrices $\mathcal{M}(w)$. Via the Riemann-Hilbert decomposition of $\mathcal{M}$ discussed above one may then further implicitly obtain the matrices $T_{\pm}$ with Poisson-structure (4.8), (4.9). Thus, together with (5.6) for solutions regular at $\rho=0$ the final situation appears rather similar to the previous chapter. This further stresses the fundamental meaning of the Poisson structure (4.10).

Let us finally look at the results of this chapter from another very intriguing point of view. In the setting with a spacelike dilaton addressed in the previous chapter we could have derived a Poisson structure not with respect to the time t but with respect to the radius r .⁹ The calculations of this chapter show that these two Poisson structures of the same model coincide for the values of the original fields on the symmetry axis $r=0$. Since these initial values provide a complete set of observables the symplectic structures are essentially equivalent. It is then tempting to speculate about further exploiting the fundamental structure (4.10) even in the case of a timelike dimensional reduction, i.e. the reduction to stationary axisymmetric spacetimes, where the canonical time is no longer present.

⁹In a covariant theory this is a rather natural idea which has been discussed in particular to describe static settings [10]. For the Schwarzschild black hole e.g. one might throw doubt upon the distinct role of time in the canonical formalism since r and t change their character being space- resp. timelike inside of the horizon.

6 The Geroch Group

With the integrals of motion $T_{\pm}(w)$ identified in the previous chapters, one can now study the symmetries they generate via their adjoint action in the canonical Poisson structure. This yields an explicit realization [34] of the Geroch group [23] with the underlying Yangian algebra (4.8), (4.9). The transformations which close into an affine algebra (the loop algebra $\hat{\mathfrak{g}}$) do not preserve the symplectic structure. This is a particular example of the Lie-Poisson action of dressing groups generated by the transition matrices of integrable models [49, 3, 39]. In contrast to the general case, here the transition matrices $T_{\pm}(w)$ themselves are integrals of motion.

Let $\Lambda(w) \in \mathfrak{g}$ be an algebra-valued function which is regular along the real w -axis and vanishes at $w \mapsto \infty$. Choose a path $\ell = \ell_+ \cup \ell_-$ encircling the real w -axis, such that $\ell_{\pm} \in H_{\pm}$ and $\Lambda(w)$ is holomorphic inside the enclosed area. Define

$$S[\Lambda] \equiv \text{tr} \left(\int_{\ell_+} T_+^{-1}(w) \Lambda(w) \text{ad}_{T_+(w)} dw + \int_{\ell_-} T_-^{-1}(w) \Lambda(w) \text{ad}_{T_-(w)} dw \right), \quad (6.1)$$

where “ad” denotes the adjoint action via the canonical Poisson structure. Since (4.8), (4.9) yield

$$\left\{ T_{\pm}^1(v), \mathcal{M}^2(w) \right\} = \left(\Omega_{\mathfrak{g}} \mathcal{M}^2(w) - \mathcal{M}^2(w) \Omega_{\mathfrak{g}}^{\eta} \right) \frac{T_{\pm}^1(v)}{v - w},$$

we obtain the symmetry action:

$$S[\Lambda] \mathcal{M}(w) = \Lambda(w) \mathcal{M}(w) - \mathcal{M}(w) \eta(\Lambda(w)). \quad (6.2)$$

This is the known infinitesimal action of the Geroch group on the matrix $\mathcal{M}$ [8]. Even though the symmetry action on the fields is highly nonlinear (cf. (6.4) and (6.5) below), on the axis $\rho = 0$ it linearizes to (6.2) and allows explicit “exponentiation” to finite transformations. This in particular shows transitivity of the Geroch group in the sector of solutions regular on the axis $\rho = 0$.

The transformations (6.2) form the loop algebra $\hat{\mathfrak{g}}$, as follows also directly after some calculation from (6.1), (4.8) and (4.9):

$$\left[S[\Lambda_1], S[\Lambda_2] \right] = S \left[[\Lambda_1, \Lambda_2] \right]. \quad (6.3)$$

Using (4.11) allows to explicitly calculate the action of $S[\Lambda]$ on the physical fields $\mathcal{V}$:

$$\begin{aligned} S[\Lambda] \mathcal{V}(x) &= \int_{\ell} dw \left(\frac{2\gamma}{\rho(1-\gamma^2)} \mathcal{V}(x) \left[\hat{\mathcal{V}}^{-1}(x, w) \Lambda(w) \hat{\mathcal{V}}(x, w) \right]_{\mathfrak{k}} \right) \\ &= - \int_{\gamma(\ell)} \gamma d\gamma \left(\mathcal{V}(x) \left[\hat{\mathcal{V}}^{-1}(x, w) \Lambda(w) \hat{\mathcal{V}}(x, w) \right]_{\mathfrak{k}} \right), \end{aligned} \quad (6.4)$$

with the algebra projection $[\cdot]_{\mathfrak{k}}$ corresponding to the decomposition (2.1) and where $\hat{\mathcal{V}}$ should be replaced by $\hat{\mathcal{V}}_1$ or $\hat{\mathcal{V}}_2$ respectively, corresponding to the choice of the dilaton ρ . The corresponding transformation of the currents $P_{\pm} \equiv \frac{1}{2}(P_0 \pm P_1)$ reads:

$$S[\Lambda] P_{\pm}(x) = \int_{\ell} dw \left(\left[\frac{2\gamma}{\rho(1 \pm \gamma)^2} \left[\hat{\mathcal{V}}^{-1} \Lambda \hat{\mathcal{V}} \right]_{\mathfrak{h}}, P_{\pm}(x) \right] \mp \frac{4\gamma^2 \partial_{\pm} \rho \left[\hat{\mathcal{V}}^{-1} \Lambda \hat{\mathcal{V}} \right]_{\mathfrak{k}}}{\rho^2 (1 \pm \gamma)^2 (1 - \gamma^2)} \right). \quad (6.5)$$

Equivalent forms of the infinitesimal symmetry transformations of the Geroch group have been stated in [25, 51, 12, 45]. E.g. it is easy to check, that the single symmetry transformations as they are made explicit in [45] may be obtained from the closed form (6.5) by means of a Taylor expansion around $w = \infty$.

From (4.12) we further directly obtain the action of $S[\Lambda]$ on the Hamiltonian H :

$$S[\Lambda] H = \text{tr} \left(\int_{\ell_+} \Lambda(w) \partial_w T_+ T_+^{-1}(w) dw + \int_{\ell_-} \Lambda(w) \partial_w T_- T_-^{-1}(w) dw \right), \quad (6.6)$$

in accordance with the formula derived in [45].

Definition (6.1) explicitly shows that this action of the Geroch group is not symplectic but Lie-Poisson, i.e. it does not preserve the Poisson structure on the phase space but on the direct product of the phase space with the symmetry group. Its role in the quantum theory remains to be elaborated, see [39] for a general discussion. In our model we could alternatively consider the pure symplectic action of the generators $T_{\pm}(w)$ via Poisson bracket since they are integrals of motion themselves. However, though they certainly act symplectic this action allows neither explicit exponentiation nor a closed form of the commutator algebra in contrast to (6.2) and (6.3).

7 Quantization: A Twisted Yangian Double at the Critical Level

So far, we have achieved a complete reformulation of the classical model (2.4) in terms of the transition matrices as new fundamental variables providing a complete set of integrals of motion. This formulation reveals integrability and the classical symmetries in a beautiful way. We can now proceed with canonical quantization of the Poisson algebra derived in the previous chapters. For the sequel we specify the algebra $\mathfrak{g}$ to be $\mathfrak{sl}(N)$, i.e. $\eta(X) = -X^t$ and $\mathfrak{h} = \mathfrak{so}(N)$. Let us recall the classical algebra of integrals of motion (4.8), (4.9). For $\mathfrak{g} = \mathfrak{sl}(N)$ it is $\Omega_{\mathfrak{sl}(N)} = \Pi_N - \frac{1}{N}I$ with the $N^2 \times N^2$ permutation operator Π_N :

$$(\Pi_N)^{ab,cd} = \delta^{ad} \delta^{bc}.$$

Accordingly we define its twisted analogue Π_N^η by

$$(\Pi_N^\eta)^{ab,cd} \equiv \left(-\Pi_N^\eta + \frac{2}{N}I \right)^{ab,cd} \equiv -\delta^{ac} \delta^{bd} + \frac{2}{N} \delta^{ab} \delta^{cd}.^{10}$$

The Poisson algebra (4.8), (4.9) then takes the form:

$$\left\{ T_{\pm}^1(v), T_{\pm}^2(w) \right\} = \left[\frac{\Pi_N}{v-w}, T_{\pm}^1(v) T_{\pm}^2(w) \right], \quad (7.1)$$

$$\left\{ T_{\pm}^1(v), T_{\mp}^2(w) \right\} = \frac{\Pi_N}{v-w} T_{\pm}^1(v) T_{\mp}^2(w) - T_{\pm}^1(v) T_{\mp}^2(w) \frac{\Pi_N^\eta}{v-w}, \quad (7.2)$$

The $T_{\pm}(w)$ are related by complex conjugation (4.2) and further restricted by $T_{\pm}(w) \in \mathbf{G}$:

$$\det T_{\pm}(w) = 1, \quad (7.3)$$

and the additional property (4.7):

$$\mathcal{M}(w) = T_+(w) T_-^t(w) = T_-(w) T_+^t(w) = \mathcal{M}^t(w). \quad (7.4)$$

Quantization of the model in terms of these variables now amounts to replacing (7.1), (7.2) by corresponding commutator relations of an $\hbar$ -graded algebra, such that these relations are compatible with the quantum analogues of (7.3) and (7.4). It admits the following essentially unique solution:¹¹

¹⁰The transposition Π_N^η here amounts to transposing just one of the two spaces in which Π_N lives.

¹¹For simplicity we use the same notation for the classical fields and the quantum operators. This should not lead to any confusion.

The quantization of the presented model for $\mathfrak{g} = \mathfrak{sl}(N)$ is given by the $*$ -algebra generated by the matrix entries of $N \times N$ matrices $T_{\pm}(w)$ subject to the exchange relations

$$R(v-w) \overset{1}{T}_{\pm}(v) \overset{2}{T}_{\pm}(w) = \overset{2}{T}_{\pm}(w) \overset{1}{T}_{\pm}(v) R(v-w), \quad (7.5)$$

$$R(v-w-i\hbar) \overset{1}{T}_{-}(v) \overset{2}{T}_{+}(w) = \overset{2}{T}_{+}(w) \overset{1}{T}_{-}(v) R^{\eta}(v-w+\frac{2}{N}i\hbar) \chi(v-w), \quad (7.6)$$

with

$$R(v) \equiv vI - i\hbar \Pi_N, \quad R^{\eta}(v) \equiv vI - i\hbar \Pi_N^{\eta}, \quad \chi(v) \equiv \frac{\Gamma\left(\frac{-i\hbar-v}{Ni\hbar}\right) \Gamma\left(\frac{(N+2)i\hbar-v}{Ni\hbar}\right)}{\Gamma\left(\frac{-v}{Ni\hbar}\right) \Gamma\left(\frac{(N+1)i\hbar-v}{Ni\hbar}\right)}. \quad (7.7)$$

The condition of unit determinant (7.3) is replaced by the quantum determinant

$$\begin{aligned} \text{qdet} T_{\pm}(w) &\equiv \sum_{\sigma \in \mathfrak{S}_N} \text{sgn}(\sigma) T_{\pm}^{1\sigma(1)}(w - (N-1)i\hbar) T_{\pm}^{2\sigma(2)}(w - (N-2)i\hbar) \dots T_{\pm}^{N\sigma(N)}(w) \\ &= 1, \end{aligned} \quad (7.8)$$

and the quantum form of the symmetry (7.4) is given by

$$\mathcal{M}(w) \equiv T_{+}(w) T_{-}^t(w) = (T_{+}(w) T_{-}^t(w))^t, \quad (7.9)$$

where transposition here simply refers to the $N \times N$ matrix entries. The $*$ -operation is defined by

$$T_{+}(w)^* \equiv T_{-}(\bar{w}), \quad (7.10)$$

and builds a conjugate-linear anti-multiplicative automorphism of the algebra (7.5)–(7.9).

Denote by $Y_{\pm}$ the algebra generated by the $T_{\pm}(w)$ respectively with exchange relations (7.5). These are two copies of the well-known Yangian algebra [14] which provide the unique quantization of the Poisson algebras given by (7.1). Compatibility with associativity is equivalent to the Yang-Baxter equation for R :

$$R_{12}(u-v) R_{13}(u-w) R_{23}(v-w) = R_{23}(v-w) R_{13}(u-w) R_{12}(u-v), \quad (7.11)$$

The corresponding compatibility of the mixed relations (7.6) with associativity is equivalent to a modified (twisted) Yang-Baxter equation for R^{η} :

$$R_{12}^{\eta}(u-v) R_{13}^{\eta}(u-w) R_{23}(v-w) = R_{23}(v-w) R_{13}^{\eta}(u-w) R_{12}^{\eta}(u-v). \quad (7.12)$$

Validity of this equation follows from the relation

$$R^{\eta}(v+\frac{2}{N}i\hbar) = -\left(R(-v)\right)^{\bar{t}}, \quad (7.13)$$

and (7.11) by applying transposition in the first space. Moreover, (7.12) remains valid under a shift of the argument in $R^{\eta}(v)$ as well as under rescaling it with a factor χ . Hence, whereas the exchange relations for $Y_{\pm}$ are uniquely given by (7.5) [14], the most general ansatz for the mixed exchange relations (7.6) is

$$R(v-w+c_1i\hbar) \overset{1}{T}_{-}(v) \overset{2}{T}_{+}(w) = \overset{2}{T}_{+}(w) \overset{1}{T}_{-}(v) R^{\eta}(v-w+c_2i\hbar) \chi(v-w). \quad (7.14)$$

The resulting algebra must respect the symmetry (7.9) of $\mathcal{M}(w)$. More precisely we demand that

$$(Y_{+} \oplus Y_{-}) \mathcal{I} = \mathcal{I} (Y_{+} \oplus Y_{-}), \quad (7.15)$$

where $\mathcal{I} \subset \mathcal{U}(Y_{+} \oplus Y_{-})$ is spanned by the antisymmetric matrix entries of $\mathcal{M}$. Relation (7.15) ensures that the antisymmetry of $\mathcal{M}$ may be consistently imposed without implying further relations. Equ.

(7.15) is not influenced by the choice of χ but uniquely determines the values of the central extensions c_j in (7.14) to be

$$c_1 = -1, \quad c_2 = \frac{2}{N}.$$

At these values the exchange relations between $T_{\pm}$ and $\mathcal{M}$ may be written in the closed form

$$\begin{aligned} R(v-w-i\hbar) T_-^1(v) \mathcal{M}^2(w) &= \mathcal{M}^2(w) R^\eta(v-w+\frac{2}{N}i\hbar) T_-^1(v) \chi(v-w) \\ R(v-w) T_+^1(v) \mathcal{M}^2(w) &= \mathcal{M}^2(w) R^\eta(v-w+(1+\frac{2}{N})i\hbar) T_+^1(v) \chi(v-w), \end{aligned} \quad (7.16)$$

and indeed imply (7.15).

The factor $\chi(v)$ in (7.6) is finally fixed from the requirement that the quantum determinants from (7.8) commute with everything such that the relations (7.8) are consistent with the algebra multiplication. It is known [28, 37] that the $\text{qdet} T_{\pm}$ span the center of $Y_{\pm}$ respectively, thus $\chi(v)$ must ensure that they also commute with $Y_{\mp}$. An essential identity for this calculation is [44]

$$\begin{aligned} \text{qdet} T_{\pm}(w) A_N &= A_N T_{\pm}^1(w) T_{\pm}^2(w-i\hbar) \dots T_{\pm}^N(w-(N-1)i\hbar) \\ &= T_{\pm}^N(w-(N-1)i\hbar) \dots T_{\pm}^2(w-i\hbar) T_{\pm}^1(w) A_N, \end{aligned}$$

where A_N denotes the antisymmetrizer in the N auxiliary spaces. Modifying the calculation for the Yangian [44] by using our mixed relations (7.6) finally leads to

$$A_N R'_{01} \dots R'_{0N} A_N T_-^0(v) \text{qdet} T_+(w) A_N = \text{qdet} T_+(w) A_N T_-^0(v) A_N R''_{01} \dots R''_{0N} A_N,$$

with

$$R'_{0j} \equiv R_{0j}(v-w+(j-2)i\hbar), \quad R''_{0j} \equiv R_{0j}^\eta(v-w+(j+\frac{2}{N}-1)i\hbar) \chi(v-w+(j-1)i\hbar).$$

Now

$$A_N R'_{01} \dots R'_{0N} A_N = \frac{v-w-2i\hbar}{v-w-i\hbar} A_N,^{12}$$

which together with (7.13) implies

$$A_N R''_{01} \dots R''_{0N} A_N = \frac{w-v-Ni\hbar}{w-v-(N-1)i\hbar} \prod_{j=1}^N \chi(v-w+(j-1)i\hbar) A_N.$$

Combining these equations yields the functional equation for $\chi(v)$ which is solved by (7.7). Uniqueness of this solution follows from its normalization at $\frac{i\hbar}{v} \rightarrow 0_-$:

$$\chi(v) \rightarrow 1 - \frac{i\hbar}{v} \left(1 + \frac{2}{N}\right), \quad \text{for } \frac{i\hbar}{v} \rightarrow 0_- ,$$

which is required in order to obtain the correct classical limit (7.2) from (7.6).

It remains to check that the $*$ -operation defined by (7.10) is indeed a conjugate-linear anti-multiplicative automorphism of the structure (7.5)–(7.9). Compatibility of (7.5) and (7.6) with (7.10) obviously follows from $R(\bar{u}) = -\overline{R(-u)}$, $R^\eta(\bar{u}) = -\overline{R^\eta(-u)}$, $\chi(\bar{u}) = \overline{\chi(u)}$ and the fact that R and R^η are symmetric under permutation of the two spaces. Invariance of the restriction of unit quantum determinant (7.8) under $*$ follows from

$$\begin{aligned} \text{qdet}(T_{\pm}(w))^* &= \sum_{\sigma \in \mathfrak{S}_N} \text{sgn}(\sigma) T_{\mp}^{N\sigma(N)}(\bar{w}) \dots T_{\mp}^{1\sigma(1)}(\bar{w}+(N-1)i\hbar) \\ &= \text{qdet}(T_{\mp}(\bar{w}+(N-1)i\hbar)), \end{aligned}$$

¹²We thank A. Molev for pointing this out.

where for the second identity we have employed one of the many properties of the quantum determinant [44]. Finally, compatibility of the symmetry relation (7.9) with $*$ follows directly from invariance of this relation under $*$:

$$(T_+(w)T_-^t(w))^* = (T_+(w)T_-^t(w))^t = T_+(w)T_-^t(w) \quad \text{for } w \in \mathbb{R} .$$

□

The algebra (7.5)–(7.9) is a new structure which in fact brings together some concepts which arose within the last years in the theory of quantum groups. The exchange relations (7.5) define the $\mathfrak{gl}(N)$ Yangian [19, 14]. The definition of the quantum determinant (7.8) is known from the $\mathfrak{sl}(N)$ Yangian [28, 37, 44]. A central extension of the type appearing in the mixed relations (7.6) has been introduced for quantum affine algebras in [48] and explicitly for the Yangian double in [30, 27]. Its value here is uniquely fixed from the requirement of compatibility with (7.9). From the abstract point of view the central extension takes the critical value at which (7.15) holds, i.e. any representation of the algebra (7.5), (7.6) factorizes over $\mathcal{I}$. The normal (untwisted) Yangian double has a critical value of the central extension at which it possesses an infinite dimensional center [48]. As we shall discuss in the next chapter, for $N = 2$ the algebra (7.5)–(7.8) is in fact isomorphic to the normal centrally extended Yangian double at critical level.

The essential new ingredient of (7.5), (7.6) is the twist¹³ η in the mixed relations which already appeared in the classical Poisson algebra. It is basically this peculiarity which requires a new representation theory to be developed.

Remark 7.1 The symmetry property (7.9) together with the definition of the $*$ -map guarantees that the object $\mathcal{M}(w)$ is symmetric and invariant under $*$. In a unitary representation it will thus form a self-adjoint operator. As such it is the natural quantum object that according to (4.5) underlies the original classical field on the symmetry axis. It satisfies closed exchange relations

$$\begin{aligned} R(v-w) \overset{1}{\mathcal{M}}(v) R^\eta(w-v + (1 + \frac{2}{N})i\hbar) \overset{2}{\mathcal{M}}(w) \\ = \overset{2}{\mathcal{M}}(w) R^\eta(v-w + (1 + \frac{2}{N})i\hbar) \overset{1}{\mathcal{M}}(v) R(w-v) \frac{\chi(v-w)}{\chi(w-v)} , \end{aligned} \quad (7.17)$$

which may be viewed as the quantization of (4.10).

8 $\mathfrak{g} = \mathfrak{sl}(2)$

To illustrate the formulas of the preceding chapter we will now discuss the particular case $\mathfrak{g} = \mathfrak{sl}(2)$. This is the model which describes the two Killing vector field reduction of pure $4d$ Einstein gravity and correspondingly already deserves strong interest from the point of view of quantum gravity. The corresponding quantum model has been introduced in [35]. Remarkably in this case there is an algebra isomorphism between our twisted and the normal Yangian double, however this is no $*$ -algebra isomorphism.

The exchange relations here read

$$R(v-w) \overset{1}{T}_\pm(v) \overset{2}{T}_\pm(w) = \overset{2}{T}_\pm(w) \overset{1}{T}_\pm(v) R(v-w) , \quad (8.1)$$

$$R(v-w - i\hbar) \overset{1}{T}_-(v) \overset{2}{T}_+(w) = \overset{2}{T}_+(w) \overset{1}{T}_-(v) R^\eta(v-w + i\hbar) \chi(v-w) , \quad (8.2)$$

¹³We are aware that the notation of “twist” has been introduced in several contexts for quantum groups in general and even for the Yangians in particular. In Ref. [46] e.g. the “twisted Yangian” denotes the Yangian for the algebra $\mathfrak{so}(N)$. However, we hope that our notation here will not cause further confusion.

with R and R^η from (7.7), where the permutation operator Π and its twisted analogue Π^η are given by

$$\Pi \equiv \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad \Pi^\eta \equiv I - \Pi^{\tilde{t}} \equiv \begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}.$$

Moreover, χ may be evaluated from (7.7)

$$\chi(v) = \frac{v(v - 2i\hbar)}{(v - i\hbar)(v + i\hbar)}.$$

The quantum determinant is given by

$$\text{qdet} T_\pm(w) \equiv T_\pm^{11}(w - i\hbar) T_\pm^{22}(w) - T_\pm^{12}(w - i\hbar) T_\pm^{21}(w) = 1; \quad (8.3)$$

the matrix product

$$\mathcal{M}(w) \equiv T_+(w) T_-^t(w) = \mathcal{M}(w)^t, \quad (8.4)$$

is symmetric under transposition and satisfies (7.17).

The particular case $N=2$ is distinguished from the higher N already on the classical level by the fact that the involution η is an inner automorphism¹⁴ generated by conjugation with

$$\sigma_2 = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}.$$

This allows to “retwist” the mixed relations (8.2) by the following transformation:

$$\tilde{T}_+(w) \equiv T_+(w) \sigma_2, \quad \tilde{T}_-(w) \equiv T_-(w). \quad (8.5)$$

These retwisted generators satisfy the exchange relations of the normal Yangian double:

$$R(v-w) \tilde{T}_\pm^1(v) \tilde{T}_\pm^2(w) = \tilde{T}_\pm^2(w) \tilde{T}_\pm^1(v) R(v-w), \quad (8.6)$$

$$R(v-w - i\hbar) \tilde{T}_-^1(v) \tilde{T}_+^2(w) = \tilde{T}_+^2(w) \tilde{T}_-^1(v) R(v-w + i\hbar) \chi(v-w), \quad (8.7)$$

at the critical level $k=-2$. At this level the center of the Yangian double becomes infinite-dimensional and is generated by the trace of the quantum current [48]

$$L(w) \equiv \left[\tilde{T}_+(w) \tilde{T}_-^{-1}(w) \right]. \quad (8.8)$$

Evaluating this in terms of our matrix $\mathcal{M}(w)$ from (8.4) yields

$$\text{tr} L(w) = \mathcal{M}^{12}(w) - \mathcal{M}^{21}(w). \quad (8.9)$$

The central extension of our structure was precisely determined by the requirement (7.15). Since for $N=2$ the subspace $\mathcal{I}$ is one-dimensional, (7.15) and an explicit calculation shows that it even lies in the center of the algebra (8.1)–(8.2). Here we see the complete agreement with the normal Yangian double at critical level. We have thus equivalence of the twisted structure (8.1)–(8.2) with the untwisted (8.6)–(8.7), however supplied with a somewhat peculiar $*$ -structure:

$$\tilde{T}_+(w)^* = \tilde{T}_-(\bar{w}) \sigma_2.$$

For higher N this equivalence does not hold. Neither is there an algebra isomorphism between (7.5), (7.6) and the normal Yangian double, nor does a center emerge at our critical level, rather criticality is expressed by (7.15).

¹⁴In contrast, for $N > 2$ the involution $\eta(X) = -X^t$ is the only outer automorphism of $\mathfrak{sl}(N)$, related to reflection of the Dynkin diagram.

Remark 8.1 Recall that classically the decomposition (4.4) provided the Riemann-Hilbert decomposition of $\mathcal{M}$ into a product of matrices holomorphic in the upper resp. the lower half of the complex plane. It is rather interesting to see how this classical holomorphy condition changes in the quantum case. Namely, assuming that the operators $T_{\pm}(w)$ still act holomorphically in $H_{\pm}$ respectively, choose some $w \in H_+$ near the real axis and integrate the mixed exchange relation (8.2) in v along some closed path in H_- which encircles $(w - i\hbar)$. Due to the nonvanishing r.h.s. this leads to a contradiction caused by the quantum effect of shifting the singularity in (8.2) by an amount of $i\hbar$. Thus the action of $T_-(v)$ can not be holomorphic in the entire H_- ; this argument shows that in fact it can not be represented holomorphically in any sub-domain of the strip $-\hbar < \Im v < 0$. In the same way it follows that the action of $T_+(v)$ can be holomorphic only in the domain $\Im v > \hbar$.

We come to an interesting observation: consistent quantization of the classical Riemann-Hilbert problem leads to a kind of “quantum Riemann-Hilbert problem”, where the contour itself (i.e. the real line) spreads out; the domains of analyticity of $T_{\pm}$ in the quantum model are $H_{\pm}^{\hbar}$, i.e. $H_{\pm}$ without a small strip along the real line. This does not imply that $T_{\pm}$ can not be defined inside of the strip $|\Im v| < \hbar$; it just means that they cannot act holomorphically inside. Therefore, it still makes sense to define the matrix $\mathcal{M}(u)$, however, as a quantum operator it loses its classical meaning as a patching matrix of the Riemann-Hilbert problem.

Remark 8.2 For explicit calculations it is sometimes useful to express the exchange relations (8.1), (8.2) in matrix components $T_{\pm}^{ab}(w)$. The mixed relations (8.2) e.g. may equivalently be written as

$$\begin{aligned} \left(1 - \frac{(i\hbar)^2}{(v-w)^2}\right) T_-^{ab}(v) T_+^{cd}(w) &= \left(1 - \frac{i\hbar}{(v-w)}\right) T_+^{cd}(w) T_-^{ab}(v) \\ &+ \frac{i\hbar}{(v-w)} \left(T_+^{ad}(w) T_-^{cb}(v) + \delta^{bd} T_+^{cm}(w) T_-^{am}(v)\right) \\ &+ \frac{(i\hbar)^2}{(v-w)^2} \delta^{bd} \left(T_+^{am}(w) T_-^{cm}(v) - T_+^{cm}(w) T_-^{am}(v)\right). \end{aligned} \quad (8.10)$$

Interpreting the matrix entries of the $T_{\pm}$ as creation and annihilation operators respectively, the r.h.s. of (8.10) can be viewed as sort of normal ordering.

9 Outlook

We have given a complete reformulation of the classical models in terms of the transition matrices of the associated linear system. In contrast to the situation in general integrable models, here the transition matrices themselves are integrals of motion. Moreover they contain a complete set of conserved charges related to the values of the physical fields on the axis $\rho=0$. The Poisson algebra of these matrices has been shown to form a semi-classical version of the Yangian double modified by appearance of a twist by the coset involution η . The transitive action of the Geroch group becomes manifest and rather transparent in this picture as the Lie-Poisson action generated by the transition matrices. This classical picture has been established for an arbitrary semisimple Lie algebra $\mathfrak{g}$ underlying the $\mathbf{G}/\mathbf{H}$ coset σ -model.

Quantization for $\mathfrak{g} = \mathfrak{sl}(N)$ led to a twisted Yangian double with central extension where the exact value of the central extension is uniquely determined from consistency, more precisely from compatibility of the structure with the symmetry of the matrix $\mathcal{M}$. For $\mathfrak{g} = \mathfrak{sl}(2)$ the structure is in fact isomorphic (but not $*$ -isomorphic) to the centrally extended Yangian double at the critical level with infinite-dimensional center.

Continuation of the programme is straightforward to outline. The representation theory of the algebra (7.5)–(7.9) must be studied. So far only the finite-dimensional representations of the normal Yangian are completely understood and classified [11]. These results might serve as basic tools to

support the first steps in exploring the relevant infinite-dimensional representations of our algebra. The hope is certainly that the requirement of unitarity with respect to the $*$ -structure (7.10) will strongly restrict the choice of representations. In [35] we have suggested a particular Fock space type representation where inspired by the linear truncation of the model the two Yangian halves of (7.5) act as creation and annihilation operators respectively. However, unitarity of this representation is not obvious, so eventually one might have to face states of negative norm; this remains to be investigated.

Once the set of possible representations has been identified and hopefully been brought to a minimum the next goal is the construction of coherent states in this framework. These states should exhibit minimal quantum fluctuations around given classical solutions. With them at hand one would finally be in position to study in detail how quantization affects the known classical solutions of gravity. In particular, this might shed some light onto the discussion about existence and properties of suited coherent states in the truncation of the model to collinearly polarized gravitational waves [1, 22]. The quantum analogue of the Geroch group is supposed to play the key role of a spectrum generating group, i.e. in accordance with the classical picture it should act transitively among the coherent states. It may be possible to shortcut the explicit construction of representation and coherent states by properly understanding the quantization [39] of this Lie-Poisson action that we have described in the classical picture.

Further open problems remain. At this stage we do not know the explicit link of the canonical approach adopted here to the isomonodromic quantization proposed in [32, 33] for the same model. Although related quantum group structures appear, the isomonodromic framework is formulated in terms of different observables, which makes the comparison even on the classical level rather non-trivial.

Since the classical picture is already formulated for an arbitrary semisimple Lie-algebra $\mathfrak{g}$ there remains the obvious task to elaborate the quantization for higher-dimensional coset spaces. As mentioned several times by now this corresponds to the models which descend from dimensional reduction of matter-coupled gravities and supergravities. The study of their quantization so far suffers simply from the fact that the theory of Yangians associated to the exceptional groups e.g. is still strongly underdeveloped — not to mention their representation theory. To describe the corresponding reduction of maximally extended $N=8$ supergravity [29] one would have to construct the related possibly centrally extended Yangian double of $E_{8(+8)}$ with a twist characterizing the maximal compact subgroup $SO(16)$.

Another highly interesting generalization would be the extension of this framework to a dimensional reduction which includes a timelike Killing vector field. At present it seems rather subtle to rigorously establish a canonical framework in a sector of stationary solutions where the canonical time-dependence has been dropped by hand. On the other hand it is certainly this sector which contains the most interesting physical solutions, in particular the black holes. Justifying relevance of the fundamental structures obtained in this paper within that context would open the doors to a profound understanding of quantum black holes.

A The Spectral Parameters

The variable spectral parameter γ is a function of the constant spectral parameter w according to

$$\gamma(x, t, w) = \gamma\left(\frac{w + \tilde{\rho}}{\rho}\right) = \frac{1}{\rho} \left(w + \tilde{\rho} - \sqrt{(w + \tilde{\rho})^2 - \rho^2} \right). \quad (\text{A.1})$$

It satisfies the differential equations

$$\gamma^{-1} \partial_\mu \gamma = \frac{1 + \gamma^2}{1 - \gamma^2} \rho^{-1} \partial_\mu \rho + \frac{2\gamma}{1 - \gamma^2} \epsilon_{\mu\nu} \rho^{-1} \partial^\nu \rho, \quad (\text{A.2})$$

as well as

$$\gamma^{-1} \partial_w \gamma = -\frac{2\gamma}{\rho(1 - \gamma^2)}. \quad (\text{A.3})$$

The inverse formula reads

$$w = \frac{1}{2} \rho \left(\gamma + \frac{1}{\gamma} \right) - \tilde{\rho}. \quad (\text{A.4})$$

The parameter γ lives on the Riemann surface defined by $\sqrt{(w + \tilde{\rho} + \rho)(w + \tilde{\rho} - \rho)}$, which is a twofold covering of the complex w -plane with x^μ -dependent branch-cut. Transition between the two sheets corresponds to $\gamma \rightarrow \frac{1}{\gamma}$. The branch-cut connects the points $w = -\tilde{\rho} \pm \rho$ on the real w -axis, which correspond to $\gamma(w = -\tilde{\rho} \pm \rho) = \pm 1$. The real w with $|w + \tilde{\rho}| < |\rho|$ are mapped onto the unit circle $|\gamma| = 1$. Real w with $|w + \tilde{\rho}| > |\rho|$ are mapped onto the real γ -axis. Dividing the w -plane into two regions $H_\pm$ and the γ -plane into four regions $D_\pm, \tilde{D}_\pm$ according to Fig. 1, $D_\pm$ and $\tilde{D}_\pm$ lie over $H_\pm$ respectively.

Figure 1: The spectral parameter planes

In particular, it is important that for fixed $w \notin \mathbb{R}$ and continuously varying ρ and $\tilde{\rho}$ the parameter γ moves within a fixed of these regions. The limits of these trajectories are given by

$$\gamma(\rho \rightarrow 0) \rightarrow \begin{cases} 0 \\ \infty \end{cases}, \quad \gamma(\rho \rightarrow \infty) \rightarrow \begin{cases} i \\ -i \end{cases}, \quad \gamma(\tilde{\rho} \rightarrow \pm\infty) \rightarrow \begin{cases} 0 \\ \infty \end{cases}. \quad (\text{A.5})$$

Another useful formula for two spectral parameters $\gamma(x, t, v)$ and $\gamma(x, t, w)$ at coinciding coordinates x, t is:

$$v - w = \frac{\rho}{2} \frac{(\gamma(v) - \gamma(w)) (\gamma(v)\gamma(w) - 1)}{\gamma(v)\gamma(w)}, \quad (\text{A.6})$$

which has e.g. been employed in the calculation of (3.4).
